

HST Observations of LyC Radiation from Galaxies & weak AGN at $2.3 \lesssim z \lesssim 5$: (How) Did they Reionize the Universe?

Rogier Windhorst (ASU) — JWST Interdisciplinary Scientist

Brent Smith, S. Cohen, R. Jansen, L. Jiang, M. Dijkstra, A. Inoue,

A. Koekemoer, R. Bielby, J. MacKenty, R. O'Connell, & J. Silk

Talk at Tel Aviv University, Monday May 25, 2015 (Tel Aviv, Israel)

All presented materials are ITAR-cleared.

Outline

- (1) HST Wide Field Camera 3 Data & Spectroscopic Sample Selection
- (2) WFC3 & ACS Lyman Continuum Stacking, Systematics, & Fluxes
 - (3) Stacked UV and Lyman Continuum Light-Profiles
- (4) SED-fitting & Dust (A_V)-distribution
- (5) LyC Escape Fractions vs. z for Faint Galaxies & Weak AGN
- (6) Summary and Conclusions

Sponsored by NASA/HST & JWST

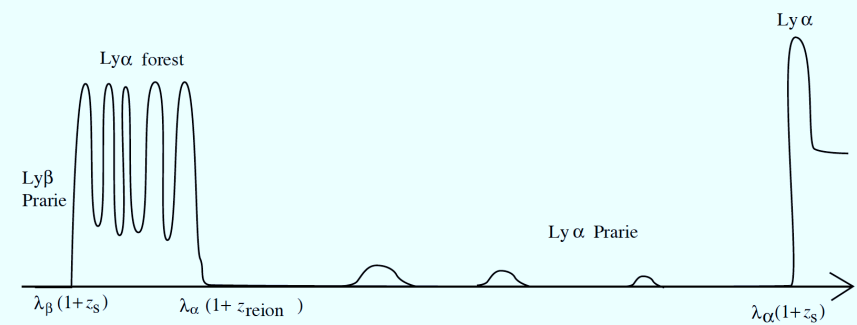

Talk is on: http://www.asu.edu/clas/hst/www/jwst/jwsttalks/irael15tau_hstlyc.pdf

DETERMINING THE REIONIZATION REDSHIFT

Spectrum

$$1 < \frac{1+z_s}{1+z_{\text{reion}}} < \frac{\lambda_{\alpha}}{\lambda_{\beta}} = 1.18$$

Cosmic Reionization (Loeb & Barkana (2001 Ann. Rev. A&A 39, 19):

[LEFT]: Universe reionized when HII-regions from first star-forming galaxies overlap: WMAP9/Planck15: This may have happened at $z \lesssim 8.8 \pm 1.5$.

[RIGHT]: Below a certain redshift ($z \lesssim 5.5?$), IGM is then transparent enough that reionizing Lyman-Continuum (LyC) radiation can reach us.

(1a) Hubble Wide Field Camera 3 (WFC3) Data

HST WFC3 and its **IR channel**: a critical pathfinder for JWST science.

Role of ACS in HST Post-SM4 Imaging Capability

ACS/WFC superior to WFC3 survey efficiency at visible-red wavelengths

WFC3/UVIS channel unprecedented UV–blue throughput & areal coverage:

- $QE \gtrsim 70\%$, $4k \times 4k$ array of $0''.04$ pixel, $FOV \simeq 2'.67 \times 2'.67$.

WFC3/IR channel unprecedented near–IR throughput & areal coverage:

- $QE \gtrsim 70\%$, $1k \times 1k$ array of $0''.13$ pixel, $FOV \simeq 2'.25 \times 2'.25$.

WFC3 filters designed for star-formation and galaxy assembly at $z \simeq 1-8$.

Early Release Science (ERS) field covers 40 arcmin^2 , $0.2-2 \mu\text{m}$ in 10 filters.

(1a) Hubble Wide Field Camera 3 (WFC3) Data

10 filters with HST/WFC3 & ACS reaching $AB=26.5-27.0$ mag ($10-\sigma$) over 40 arcmin^2 at $0.07-0.15''$ FWHM from $0.2-1.7 \mu\text{m}$ (UVUBVizYJH). (JWST adds $0.05-0.2''$ FWHM imaging to $AB \simeq 31.5$ mag (1 nJy) at $1-5 \mu\text{m} + 0.2-1.2''$ FWHM at $5-29 \mu\text{m}$, tracing young+old SEDs & dust)

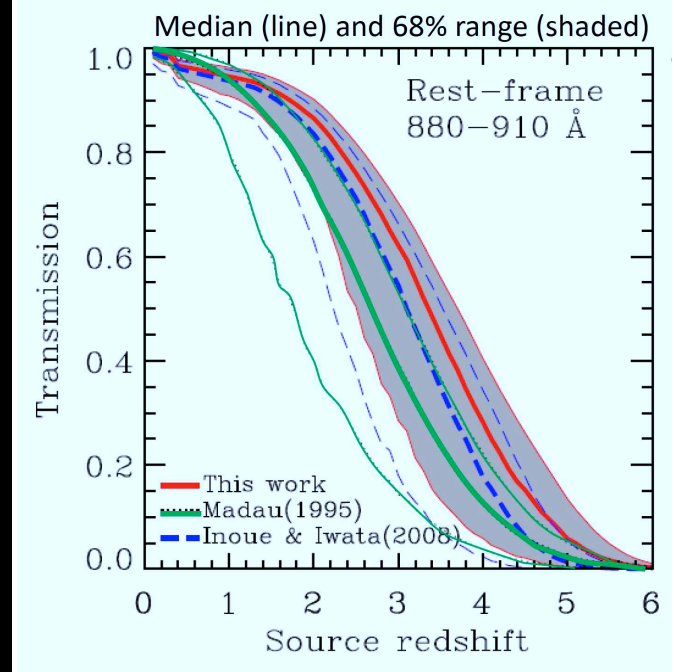

[LEFT] Composite rest-frame far-UV spectra of: SDSS QSOs at $z \simeq 1.3$ (van den Berk et al. 2001); LBGs at $z \simeq 2-4$ (Bielby et al. 2013, Ly α emitters, & absorbers), and LBGs at $z \simeq 3$ (Shapley et al. 2003).

- WFC3/UVIS F225W, F275W, F336W, and ACS/WFC F435W filters can capture LyC ($\lambda < 912 \text{ \AA}$) at $z \geq 2.26$, $z \geq 2.47$, $z \geq 3.08$, and $z \geq 4.35$.
- Lower z -bounds chosen such that *no* $\lambda > 912 \text{ \AA}$ light is sampled below the filter's red edge (defined at 0.5% of peak transmission).

[RIGHT] Total observed throughput curves, designed to maximize throughput and minimize red-leak, which is $\lesssim 0.6\%$ of LyC signal.

- Filter red-leak wing ($\lambda \gtrsim 3648 \text{ \AA}$) is $\lesssim 3 \times 10^{-5}$ of peak transmission.

[LEFT] Cen & Kimm (2015): PDFs of mean f_{esc} over “ N_{stack} ” objects: high-mass (top) & low-mass (bottom) at $z=4$ (left) & $z=6$ (right).

- Mean f_{esc} from weighted number of photons mimics SED stacking of galaxy LyC data with true mean f_{esc} listed. ERS has $N_{stack}=11-37$.

[RIGHT] Inoue et al. (2014, MNRAS 442, 1805): IGM transmission models for f_{esc} calculations: Red is the median and grey the 68% range, based on MC simulations of IGM attenuation vs. z .

Uses updated absorber function + available data on Ly α forest, Damped Lyman Alpha (DLA) & Lyman Limit Systems (LLS) mean-free paths.

F225W

F275W

F336W

The first, hardest part was to get the WFC3 astrometry right:

- Pre-flight 2009 ERS geo-distortion had $\lesssim 0''.45$ offsets at image borders compared to GOODS v2.0 (Windhorst et al. 2011 ApJS, 193, 27).
- In-flight 2013 geo-distortion correction yielded excellent registration of all WFC3/UVIS tiles to the ACS F435W mosaics (Kozhurina et al. 2013).
- Compared to GOODS, all offsets are now $\lesssim 0''.02 \pm 0.06$ (rms) in all LyC filters (Smith et al. 2015) — this no longer blurs any LyC signal!
- Any LyC signal can now be measured and stacked, including removal of all foreground interlopers ($AB \lesssim 27.5$), and measurement of LyC light-profiles.

Residual sky-background levels in the drizzled WFC3/UVIS ERS mosaics:

- Black lines: best fit to the 2009 ERS v0.7 mosaics of Windhorst et al. (2011), which used pre-flight thermal vacuum flat-fields.
- Red lines: current mosaics (ERS v2.0; Smith et al. 2015), using best available on-orbit calibrations.
- Global *residual sky-background levels* (in ADU/sec) remaining after drizzling the ERS mosaics are $\sim 30.29, 29.99, \text{ and } 28.15 \text{ mag arcsec}^{-2}$.
- These are removed in three stages: globally during drizzling ($Z_{\text{odi}} \simeq 25.5 \text{ mag arcsec}^{-2}$), locally before stacking, and again locally after stacking (to do the photometry). **This is absolutely critical for optimal LyC stacking.**
- Final $71 \times 71 \text{ pix } (6''.39 \times 6''.39)$ LyC stacks allow *residual* local sky-subtraction to $\lesssim 32.3 \text{ mag arcsec}^{-2}$.

(1b) Hubble WFC3 ERS — Spectroscopic Sample Selection

Comparison of redshift reliability (spectrum quality) assessments, from best (0.0) to poorest (2.0), by five co-authors [BS, RAW, SHC, RAJ, and LJ]:

- Measuring LyC escape fractions of $f_{esc} \simeq 6.0\%$ at $\gtrsim 3\sigma$ requires low interloper fraction (Siana⁺ 2015; Vanzella⁺ 2015).
- Mask-out all interlopers from 10-band ERS mosaics to $AB \lesssim 27.5$ mag.
- Use all VLT, Keck, & HST grism spectra to get most reliable samples:
- “Gold” sample: highest fidelity (grades=0–0.63): spec-z’s very likely correct.
- “Silver” sample: next highest fidelity (0.64–1.33), with z’s likely correct.

Absolute and apparent WFC3/IR F125W (*J*-band) magnitude distributions of the Gold and combined Gold + Silver samples:

- The F125W filter samples rest-frame near-UV emission at $2.26 \lesssim z \lesssim 5$. It serves as a proxy for restframe M_{AB} (1650Å) for flat spectrum objects.
- The blue dotted curve indicates the faint-end power-law slope of 0.16 dex/mag of the galaxy number counts of W11.
- Sample incompleteness for $AB \gtrsim 24$, or M_{AB} (1650) $\gtrsim -21$ mag.
- Any LyC AB-fluxes & f_{esc} -values are only valid for these luminosities!

● (2) WFC3 & ACS Lyman Continuum Stacking, Systematics, & Fluxes

stack1 $avg_{tot} = 9.39e-06$ $med_{tot} = 8.91e-06$
 $mode_{tot} = -5.73e-05$ $\sigma_{avg} = 5.02e-06$

stack2 $avg_{tot} = 6.00e-06$ $med_{tot} = 6.50e-06$
 $mode_{tot} = -7.58e-05$ $\sigma_{avg} = 7.15e-06$

stack1uv $avg_{tot} = 3.18e-03$ $med_{tot} = 3.17e-03$
 $mode_{tot} = 1.17e-03$ $\sigma_{avg} = 1.04e-04$

stack2uv $avg_{tot} = 3.16e-03$ $med_{tot} = 3.14e-03$
 $mode_{tot} = 9.47e-04$ $\sigma_{avg} = 8.55e-05$

stack3 $avg_{tot} = 4.20e-05$ $med_{tot} = 4.12e-05$
 $mode_{tot} = -8.69e-05$ $\sigma_{avg} = 6.70e-06$

stack4 $avg_{tot} = 1.61e-03$ $med_{tot} = 1.61e-03$
 $mode_{tot} = -4.04e-05$ $\sigma_{avg} = 6.97e-05$

stack3uv $avg_{tot} = 3.35e-03$ $med_{tot} = 3.35e-03$
 $mode_{tot} = 1.73e-03$ $\sigma_{avg} = 1.18e-04$

stack4uv $avg_{tot} = 2.76e-03$ $med_{tot} = 2.76e-03$
 $mode_{tot} = 1.29e-03$ $\sigma_{avg} = 1.26e-04$

“Tic-tac-toe” sky-background analysis of 71×71 pixel ($6''39 \times 6''39$) stacks: LyC [left 4 panels] and UVC [right 4 panels].

● Large-scale gradients in residual sky-background left in drizzled images are $5\text{--}40 \times$ fainter than the *global* remaining sky residuals in previous Fig.

● Residual sky-gradients on 71×71 pixel scales are fainter than ~ 32.3 mag arcsec $^{-2}$ across the “tic-tac-toe” apertures. This is fainter than the LyC SB-signal where this can be measured, but does constitute a (fundamental?) limit to how many images can be stacked.

Galaxies without AGN, $2.3 \lesssim z \lesssim 6$  $z=2.26-2.47$ $z=2.47-3.08$ $z=3.08-4.35$ $z=4.35-6$ WEIGHTED ALL: $z=2.26-6$.

[Top Row]: All galaxies in combined Gold Galaxy sample: N=51;

[Bottom Row]: All galaxies in combined Gold+Silver sample: N=118.

[Right 2x2 panels]: Weighted “stack-of-stacks” over all 4 LyC filters: best visualizes LyC of galaxies at $z \simeq 2.3-5.5$. Formal detection S/N -ratios:

$\gtrsim 6.8\sigma$ ($\sim \sqrt{51} \times 1.0\sigma$ above sky), and $\gtrsim 13\sigma$ ($\sim \sqrt{118} \times 1.2\sigma$).

Equivalent to 22–236 orbit stacks with HST, respectively!

Circles: $r=8$ ($0''.72$), 13 pix ($1''.17$), centered on the UVC emission.

Galaxies without AGN, Gold sample

$z=2.26-2.47$

$z=2.47-3.08$

$z=3.08-4.35$

$z=4.35-6.$

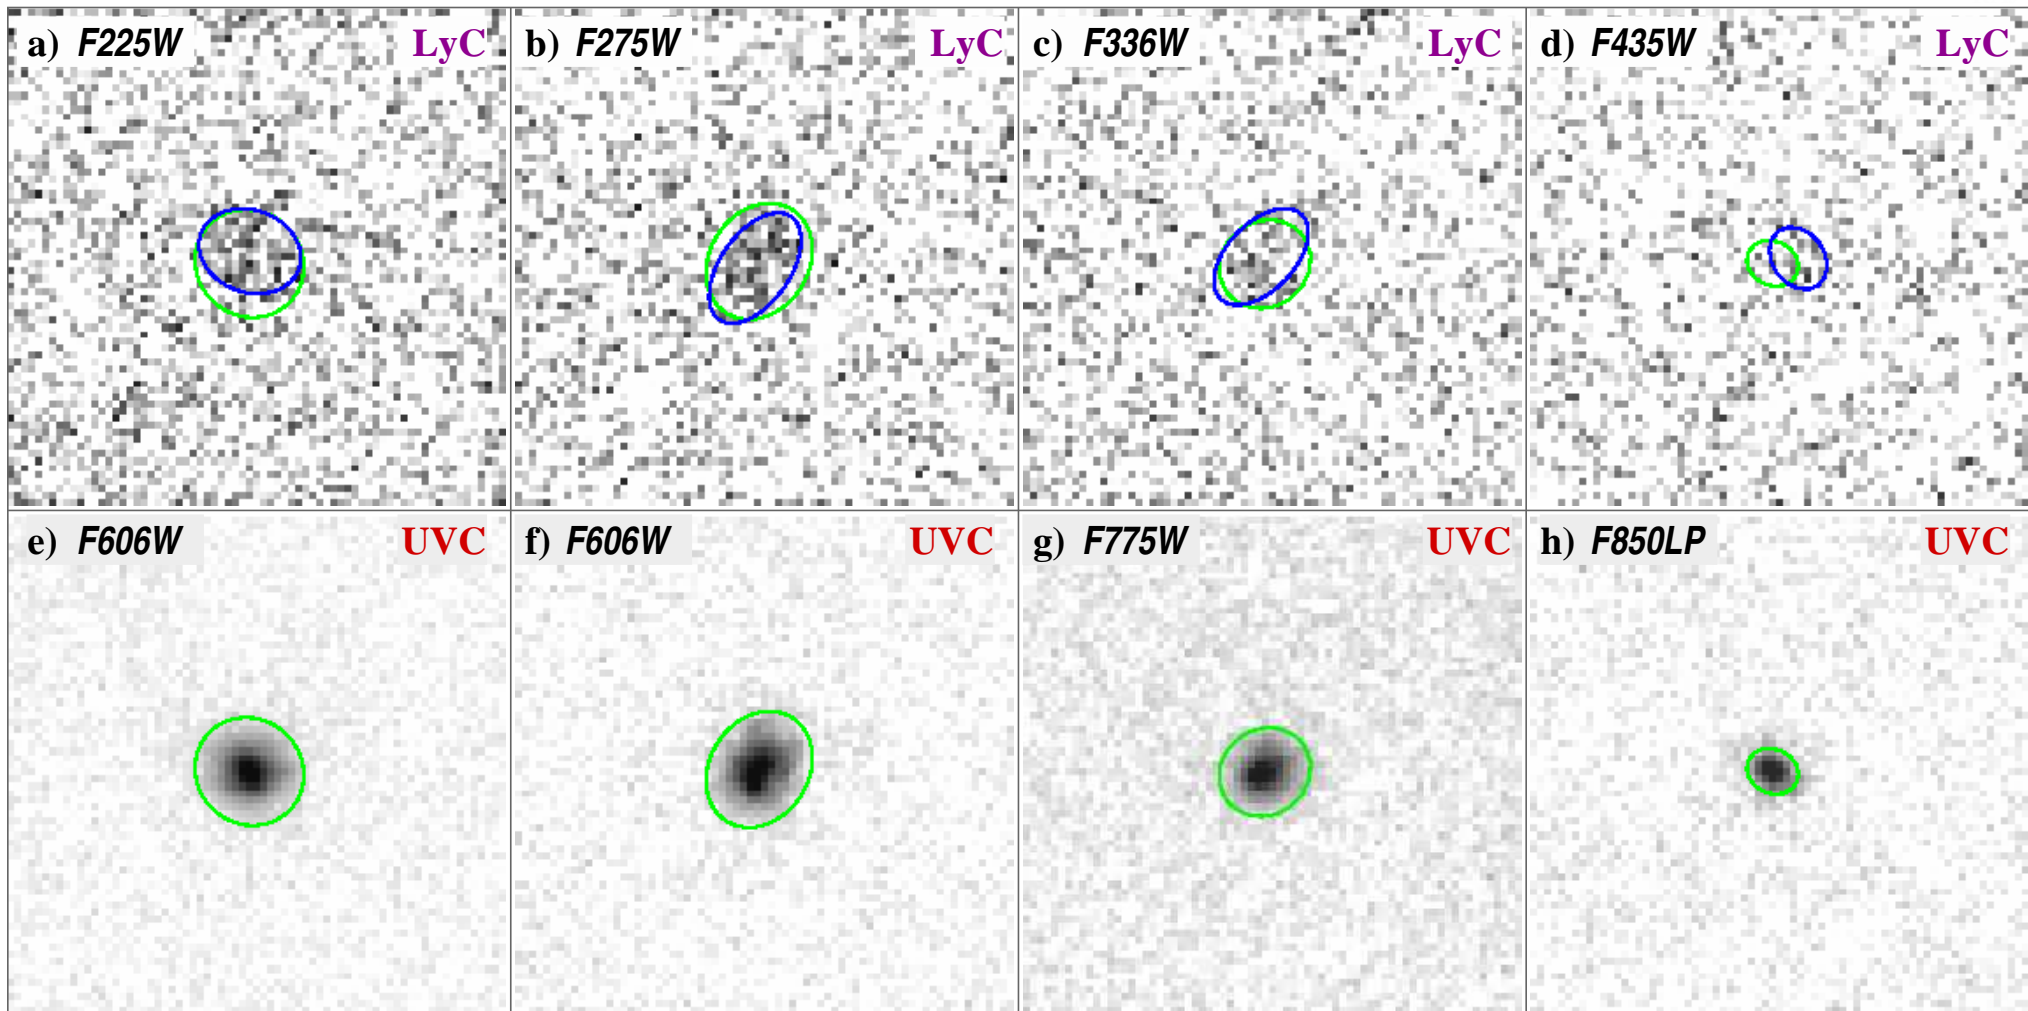

Galaxies without AGN in Gold sample.

Top row: Ly-Continuum stacks, Bottom Row: UV-Continuum stacks.

Blue: SEXTRACTOR LyC apertures, $\gtrsim 1\sigma$ in $\gtrsim 4$ connected pixels.

Green: SEXTRACTOR MAG_AUTO apertures using UVC centroids+apertures.

Galaxies without AGN, Gold+Silver sample

$z=2.26-2.47$

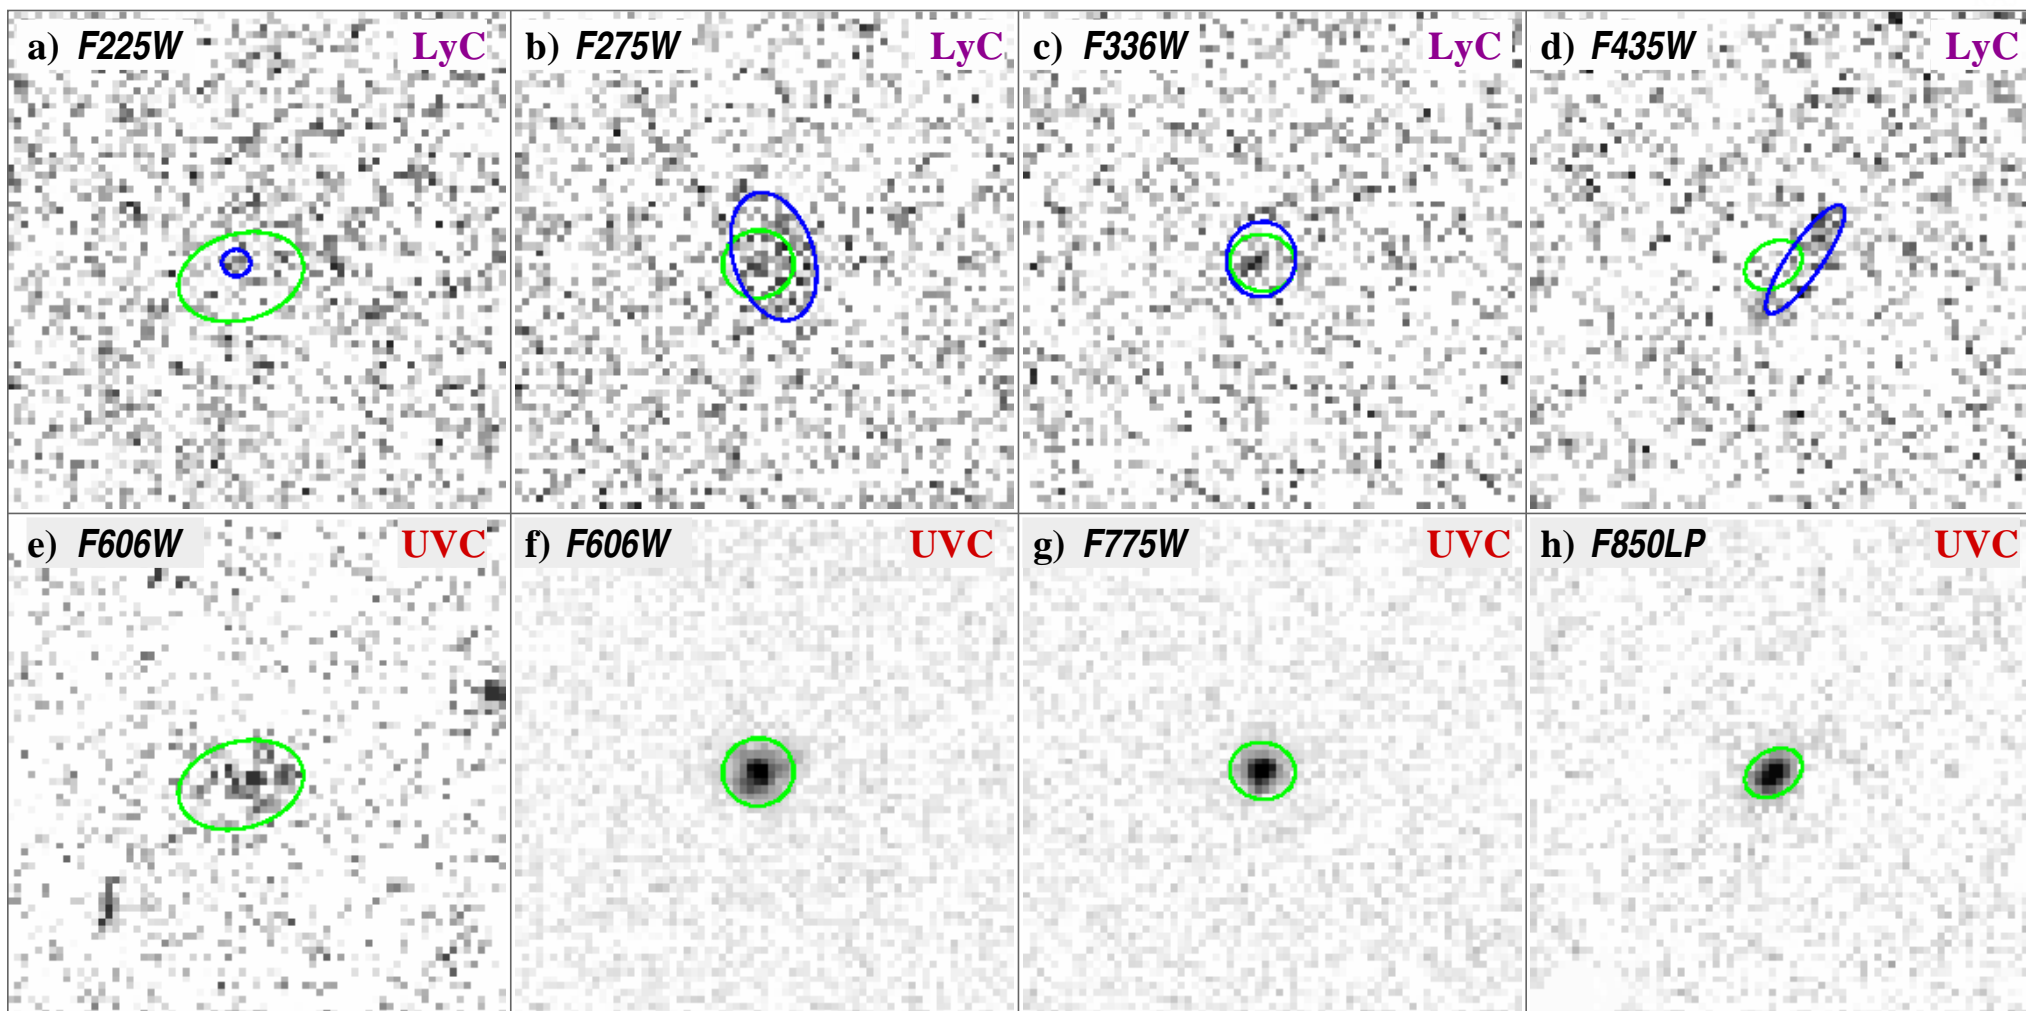

$z=2.47-3.08$

$z=3.08-4.35$

$z=4.35-6.$

Galaxies without AGN in combined Gold + Silver sample.

Galaxies with AGN, Gold sample

$z=2.26-2.47$

$z=2.47-3.08$

$z=3.08-4.35$

$z=4.35-6.$

Galaxies hosting weak AGN in Gold sample.

[Lower Left]: $N=1$ AGN with background objects shown before masking-out.

All galaxies, Gold sample

$z=2.26-2.47$

$z=2.47-3.08$

$z=3.08-4.35$

$z=4.35-6.$

All Objects (Galaxies + Weak AGN) in Gold sample.

All Galaxies, Gold+Silver sample

$z=2.26-2.47$

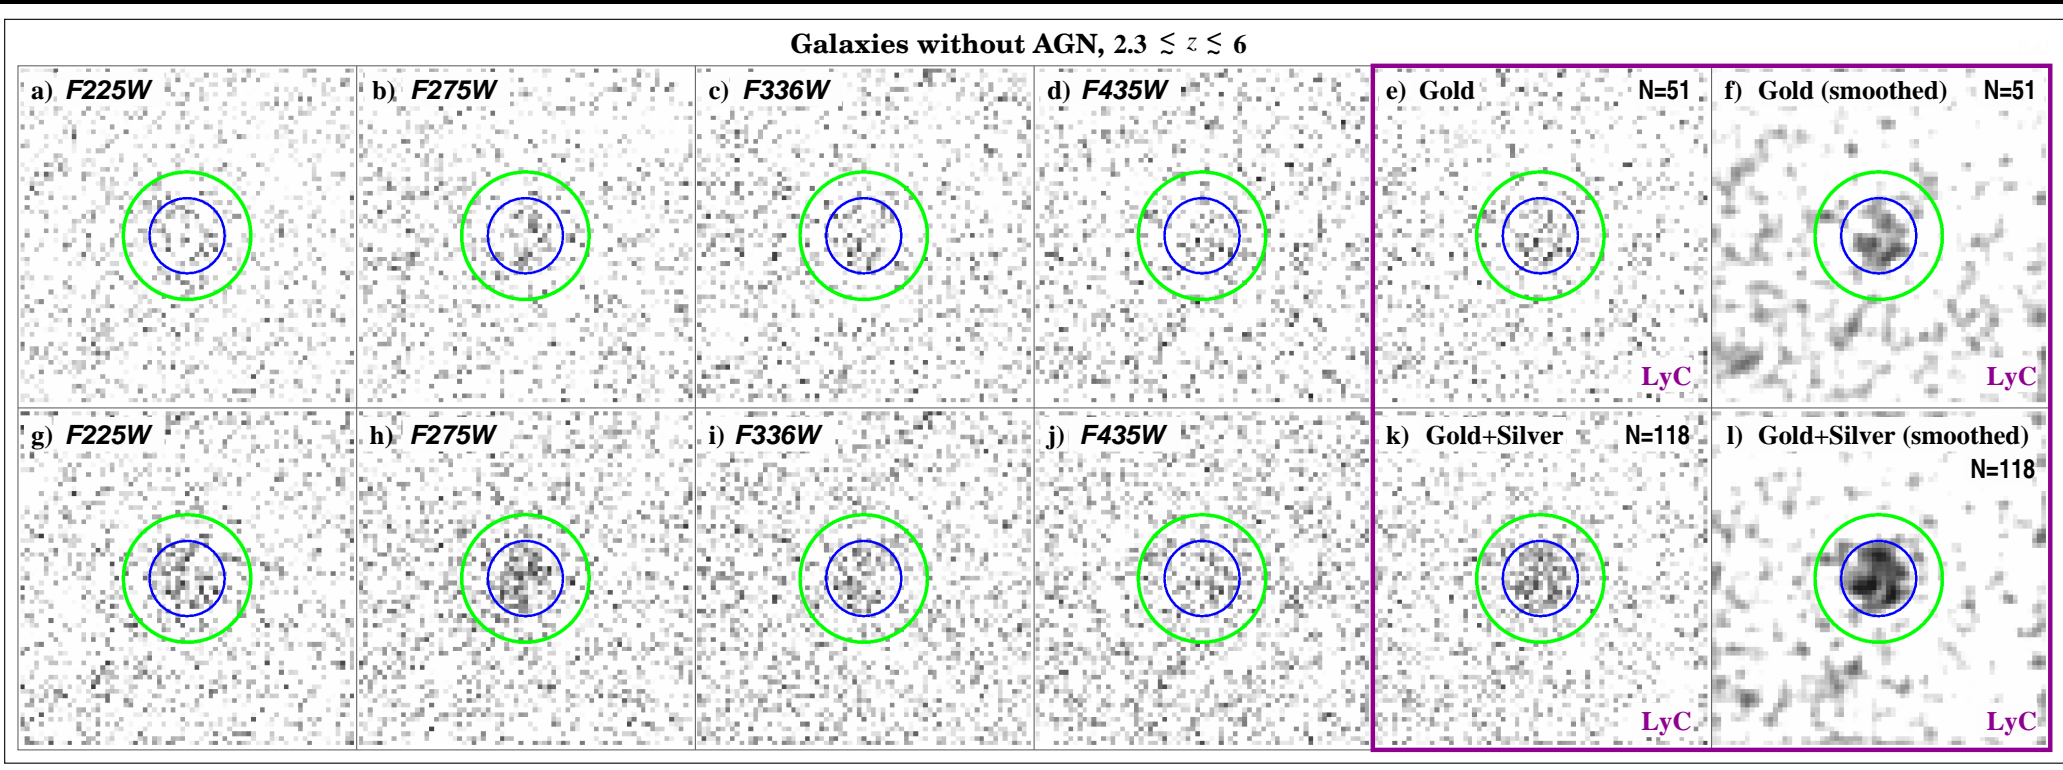

$z=2.47-3.08$

$z=3.08-4.35$

$z=4.35-6.$

All Objects (Galaxies + Weak AGN) in Gold+Silver sample.

● (3) Stacked UV and Lyman Continuum Light-Profiles

$z=2.26-2.47$

$z=2.47-3.08$

$z=3.08-4.35$

$z=4.35-6$

WEIGHTED ALL: $z=2.26-6$.

[Top Row]: All galaxies in combined Gold Galaxy sample: N=51;

[Bottom Row]: All galaxies in combined Gold+Silver sample: N=118.

- The faint LyC emission has a very flat SB-distribution with radius:
- *On average* escapes along few random sight-lines through a porous ISM?
- Not centrally concentrated with few clear sight-lines per galaxy.
- Likeliest escape paths may be somewhat offset from galaxy center.

[Top Curves]: Radial SB-profiles of non-ionizing UVC (solid).

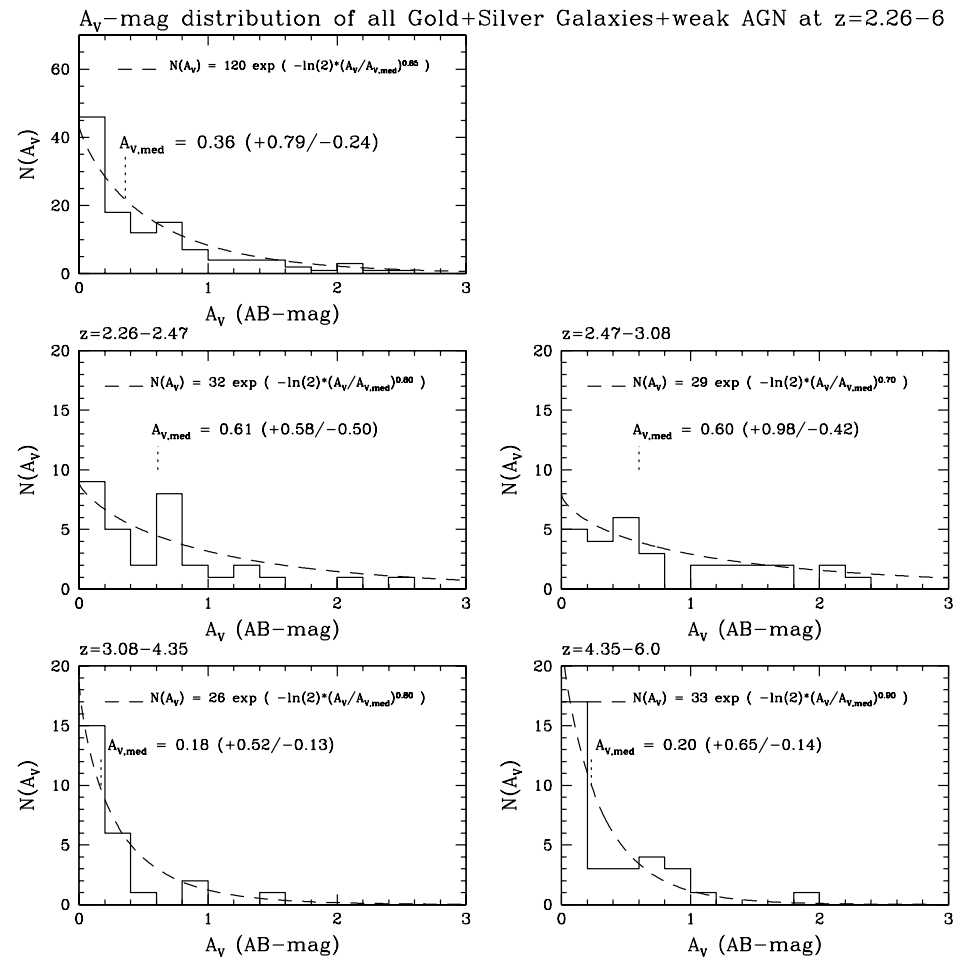

[Bottom Curves]: Radial SB-profiles of LyC signal (dashed):

● All LyC SB-profiles are extended compared to the PSFs (dotted).

Horizontal black dashed line is the 1σ SB-limit of $\sim 32 \text{ mag arcsec}^{-2}$.

Light-blue dot-dashes is $z=2.68$ UVC-scattering model with ISM porosity and escaping LyC increasing as: $f_{\text{cov}}(r) = \mathcal{N} \exp\{- (r/10 \text{ kpc})^x\}$.

● (4) Spectral Energy Distribution (SED)-fitting & Dust (A_V)-distribution

[LEFT]: Best-fit A_V from 10-band SEDs for all ERS galaxies (black dots).

Circles: galaxies; Asterisks: AGN at: $z=2.37$, $z=2.68$, $z=3.45$, $z=5.1$.

[RIGHT]: Adopted distributions $N(A_V)$ for total Gold + Silver LyC sample (top), and for each of the four redshift bins:

Median A_V increases from ~ 0.2 at $z=5.1-3.5$ to ~ 0.6 at $z=2.67-2.37$.

Best-fit A_V from 10-band SEDs for all ERS galaxies (black dots).

- Galaxies+AGN with $z_{spec} = 2.37-2.68$ represent $N(A_V)$ distribution.
- Spectroscopically selected galaxies + AGN at $z=3.45-5.1$ miss $\sim 45\%$ of dusty ($A_V \gtrsim 1$ mag) objects at $z \gtrsim 3$.
- Our f_{esc} -value calculations vs. redshift will correct for this.

● (5) LyC Escape Fractions vs. z for Faint Galaxies & Weak AGN

PDFs of absolute & relative f_{esc} -values (Inoue⁺ 2014 MC), folding LyC fluxes $\pm 1\sigma$ errors through 10^9 random LOS of IGM transmission.

● Filled triangles indicate the resulting modal and circles the average f_{esc} -values in each PDF. Tick-marks show the $\pm 1\sigma$ -range.

[Left]: Relative f_{esc} -z: Published + ERS Gold & Gold+Silver samples.
 Shaded bounded by: $f_{esc} \simeq (0.02 \pm 0.01) \cdot (1+z)^{1.0 \pm 0.5}$ does not fit well.
 Simple $\tanh[\log(1+z)]$ captures more sudden f_{esc} -increase at $z \gtrsim 2.5-3$.
 [Dashed: Same, corrected for $\sim 45\%$ missing SMGs ($A_V > 1$) at $z \gtrsim 3.1$].
 [Right]: Same for 12 AGN in ERS (+Bridge⁺ 2010) available thus far.
 Object-weighted ratio of tanh-curves suggests f_{esc} (galaxies) high enough to dominate reionization at $z \gtrsim 3$, while AGN may dominate at $z \lesssim 2.5$.

WFC3 ERS 10-band redshift estimates accurate to $\lesssim 4\%$ with small systematic errors (Hathi et al. 2010, 2013), resulting in a reliable $N(z)$.

- Measure masses of faint galaxies to $AB=26.5 \text{ mag}$, tracing the process of galaxy assembly: downsizing, merging, (& weak AGN growth?).

\Rightarrow Median redshift in (medium-)deep fields is $z_{med} \simeq 1.5-2$.

- HUDF shows WFC3 $z \simeq 7-9$ capabilities (Bouwens⁺ 2014; Yan⁺ 2010).

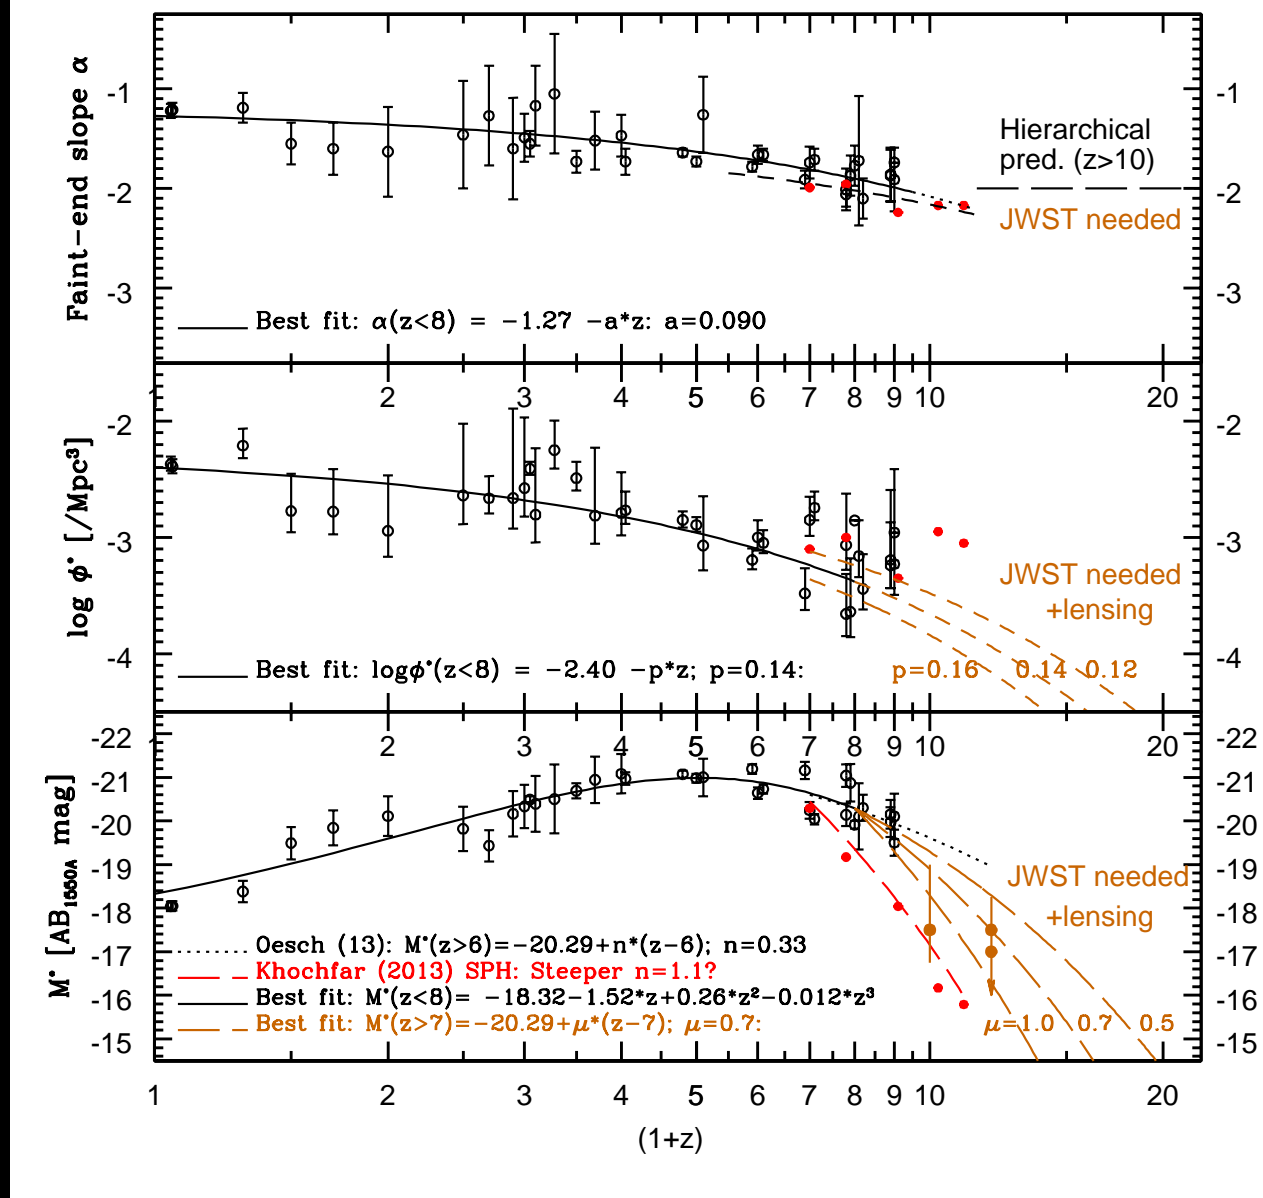

- JWST will trace mass assembly and dust content $\lesssim 5 \text{ mag}$ deeper from $z \simeq 1-12$, with nanoJy sensitivity from $0.7-5 \mu\text{m}$.

(5b) Can JWST see most of the Reionizing sources?

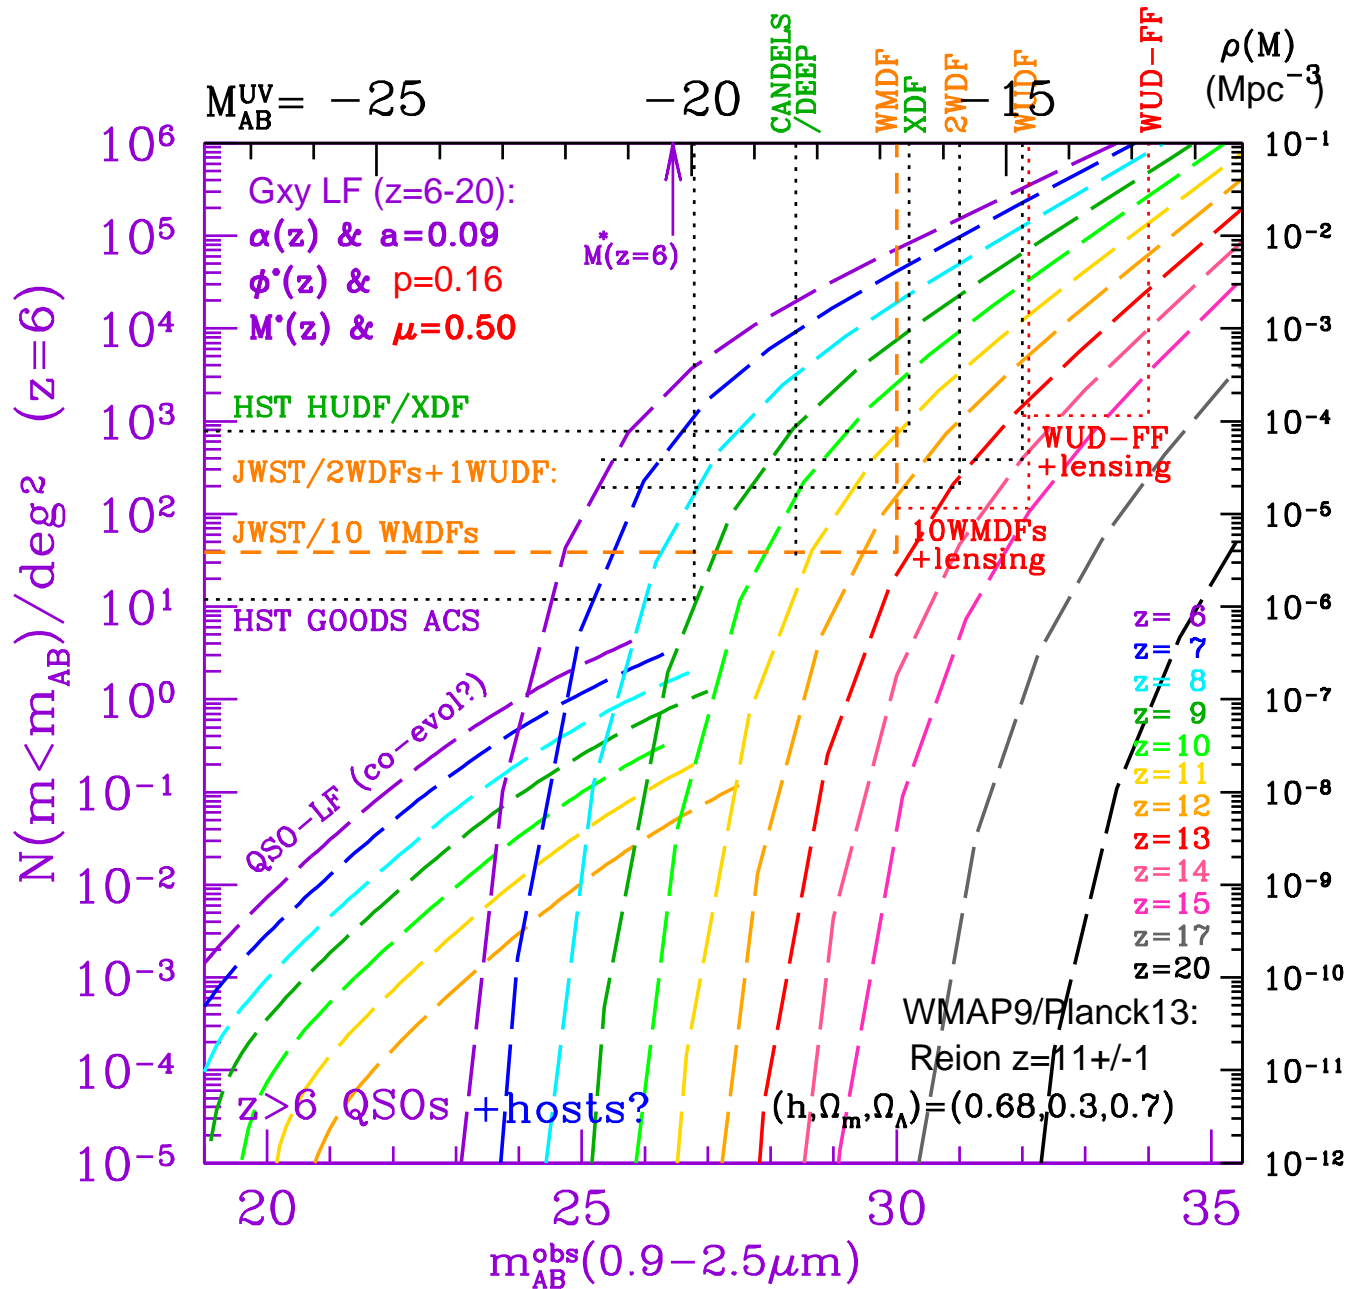

1.6 μ m counts (Windhorst⁺2011). [F150W, F225W, F275W, F336W, F435W, F606W, F775W, F850LP, F105W, F125W, F140W not shown].

- Faint-end near-IR count-slope $\simeq 0.16 \pm 0.02$ dex/mag \iff
 Faint-end LF-slope $\alpha(z_{med} \sim 1.6) \simeq -1.4 \implies$ reach $M_{AB} \simeq -14$ mag.
- 800-hr WUDF can see $AB \lesssim 32$ objects: $M_{AB} \simeq -15$ (LMCs) at $z \simeq 11$!
- Lensing will change the landscape for JWST observing strategies (WUDFF).

- Evolution of Schechter UV-LF: faint-end LF-slope $\alpha(z)$, $\Phi^*(z)$ & $M^*(z)$:
- For JWST $z \gtrsim 8$, expect $\alpha \lesssim -2.0$; $\Phi^* \lesssim 10^{-3}$ (Mpc⁻³) (Bouwens⁺ 14).
 - HUDF: Characteristic M^* may drop below -18 or -17.5 mag at $z \gtrsim 10$.
- ⇒ Will have significant consequences for JWST survey strategy.

- Schechter LF ($6 \lesssim z \lesssim 20$) with best-fit $\alpha(z)$, $\Phi^*(z)$, $M^*(z)$ & $\mu=0.50$.
 Area/Sensitivity for: HUDF/XDF, 10 WMDFs, 2 WDFs, & 1 WUDF.
- Will need lensing targets for WMDF-WUDFF to see $z \simeq 12-15$ objects.

(6) Summary and Conclusions

(1) HST can measure LyC for galaxies + weak AGN at $z \simeq 2.26\text{--}5.5$.

- WFC3 and ACS filters designed with low-enough redleak to enable this.
- Samples of sufficient size ($N=11\text{--}118$) need to be stacked to see LyC signal.
- Astrometry/registration and sky-background subtraction must be carefully done in various stages.
- Subtle residual sky-gradients and other systematics ultimate limitation to LyC stacking (at $\gtrsim 32.3$ mag arcsec $^{-2}$).
- Deepest 10-band images at HST resolution critical to mask-out all foreground interlopers to $AB \lesssim 27.5$ mag.
- Careful spectroscopic redshift selection critical for reliable samples.
- Must correct results for M_{AB} and A_V -biases that result from the necessary spectroscopic selection.

(2) LyC signal detected in sub-samples of $N=11-37$ objects at $z=2.26-5.5$.

- Detections of AB(LyC) generally better than $\gtrsim 3-4\sigma$ (AB $\simeq 29.5-31$ mag).
- Weak AGN have ~ 1 mag brighter AB(LyC), but are $4-10\times$ less numerous than galaxies.
- Stacked LyC SB-profiles are on average much flatter than the UV-continuum Sersic-profile.
- LyC may escape along few random sight-lines, offset from the average galaxy center.
- Non-Sersic LyC SB-profiles may indicate that the ISM porosity increases with r .

(3) Resulting f_{esc} -values show rapid “tanh[log(1+z)]” increase at $z \gtrsim 2.5$.

- Dust-corrected SED-fits and MC simulations are essential to interpret this sudden drop in $f_{esc}(z)$.

- Best-fit 10-band ERS SEDs suggests A_V increases from $z \sim 6$ to $z \simeq 2.3$.

- Spectroscopic selection at $z=2.37-2.68$ follows field galaxy A_V , but at $z=3.45-5.1$ misses $\sim 45\%$ of dusty objects.

- This explains part, but not all, of the sudden f_{esc} -increase at $z \gtrsim 2.5$: Accumulating $A_V(t)$ may shut down $f_{esc}(z \lesssim 3)$.

- Object-weighted ratio of tanh-curves suggests f_{esc} (galaxies) high enough to dominate reionization at $z \gtrsim 3$, while AGN may take over at $z \lesssim 2.5$.

Stacking Tests, Gold sample

$z=2.37$, $z=2.68$, $z=3.45$,
 $z=5.1$ Gold stacks;

Same Gold stacks af-
ter random 90° rotation;

First independent data
halves Gold stacks;

Second independent
data halves Gold stacks;

Random sky-stacks
to verify null-signal.

Stacking Tests, Gold+Silver sample

$z=2.37$, $z=2.68$, $z=3.45$,
 $z=5.1$ Silver stacks;

Same Silver stacks after
random 90° rotation;

First independent data
halves Silver stacks;

Second independent
data halves Silver stacks;

Random sky-stacks
to verify null-signal.

Detector location of “high-CTE” and “low-CTE” sub-samples: [LEFT]: WFC3/UVIS F225W, F275W, F336W. [RIGHT]: ACS/WFC F435W.

Green regions are closest to parallel read-out amplifier. Red regions are furthest from amplifiers, and may suffer more from CTE-degradation.

- Filled circles show marginal LyC signal in individual objects:
- These are fairly uniformly distributed across individual CCDs.

Average stacked LyC diff: $\Delta(\text{Lower-CTE}-\text{High-CTE}) \simeq 0.5 \pm 0.35$ mag.

⇒ Less than four months after WFC3’s launch, CTE-induced systematics are not yet larger than the random errors in the LyC signal.
